## 1999 KANSAS SOYBEAN PERFORMANCE TESTS

### INTRODUCTION

#### TEST OBJECTIVES AND PROCEDURES

Soybean performance tests are conducted each year to provide information on the relative performance of new and established varieties and brands at several locations in Kansas.

Seeds for tests are from certified growers, agricultural experiment stations, and private seed companies (Table 1). Seed quality, including such factors as purity and germination, can be important in determining the performance of a variety. Soybean seed used for public and private entries in the Kansas Crop Performance Tests is prepared professionally and usually meets or exceeds Kansas Crop Improvement Certification standards. Relative performance of a given variety comparable to that obtained in these tests is best assured under similar environmental conditions and cultural practices and with the use of certified or professionally prepared seed. All companies known to be developing and marketing soybean varieties or brands are invited to submit test seed; interested companies enter on a voluntary, fee-entry basis.

Companies were invited to enter Roundup-resistant varieties either in the standard trials or in separate Roundup trials. A few non-Roundup-resistant varieties, which received standard herbicides, were included in most of these separate trials as checks. Most of the Roundup-resistant varieties were entered in the Roundup tests, but several also were entered in the standard tests. An asterisk \* following the entry name is used to identify Roundup-resistant entries in the tables.

Entries were planted in four-row plots with rows 30 inches apart, except in the Ellis County test where row width was 24 inches,

and replicated three or four times each. Seeding rate ranged from seven to 12 seeds per foot of row. The center two rows of each plot were harvested for yield. Harvested row lengths ranged from 13 to 32 feet, depending on location. Cultural practices used and rainfall received at each test location are given in Table 2. Results from this year's tests are presented in Tables 3 through 24. Relative yields of each entry from all locations are shown in Table 25. Results of the tests also can be found at the Kansas crop performance tests' homepage: <http://www.ksu.edu/kscpt>.

For the past several years, Experiment Station personnel have conducted trials to evaluate the performance of soybean varieties when grown in soil infested with soybean cyst nematode (SCN). A summary of results for the past 4 years is included in Table 12 (Cherokee County). Entries resistant and susceptible to SCN are evaluated in these trials. Two additional trials also from southeast Kansas, a river-bottom test (Table 23) and a double-cropped test (Table 24) are included in the report this year.

#### DATA INTERPRETATION

Yields are recorded as bushels per acre (60 pounds per bushel) adjusted to 13% moisture content, when moisture data are available. Seed yield also is expressed as a percentage of the test average to assist in identifying entries that consistently produce better than the average yield.

Maturity is the date on which 95% of the pods have ripened (browned). Delayed leaf drop and green stems are not considered when assigning maturity. About 1 week of good drying weather after maturing is needed

before soybeans are ready to harvest.

Lodging is rated at maturity by the following scores:

- 1 - Almost all plants erect
- 2 - All plants slightly leaning or a few plants down
- 3 - All plants leaning moderately (45%) or 25 to 50% of plants down
- 4 - All plants leaning considerably or 50 to 80% plants down
- 5 - Almost all plants down

Height is the average length from the soil surface to the top of the main stem of mature plants.

#### VARIETY OR BRAND SELECTION

Performance of soybean varieties or brands varies from year to year and from location to location, depending on such factors as weather, management practices, and variety adaptation. When selecting varieties or brands, one should carefully analyze their performance for 2 or more years across locations. Performance averaged over several years will provide a better estimate of genetic potential and stability than will 1 year's information.

Small differences in yield between any two varieties or brands usually are not important. Within maturity groups at each location, an LSD (least significant difference) was calculated. The significance level used to calculate the LSD was 10%. Unless two varieties differ in yield by more than the LSD, genetic yield potential of one entry cannot be considered superior to that of another.

At a few sites where entries were grouped and could be analyzed by maturity, an

additional LSD value is listed at the bottom of the table. This LSD value can be used to compare the yields of entries in different maturity groups. For example, the yield of an entry in the group III test at Harvey County can be compared with the yield of an entry in the group IV test at the same location to determine if they are statistically different.

The coefficient of variability (CV) represents an estimate of the precision in the replicated yield trials. A CV of less than 10% indicates a good test with a high level of reliability. CVs ranging from 10 to 15% are usually acceptable for performance comparisons. CVs greater than 15% generally lack sufficient precision to provide any more than a rough guide to cultivar performance. In those tests in which the precision was insufficient to statistically compare performance among the entries, the LSD value has been replaced with the designation, NS, indicating that seed yields were not significantly different.

#### 1999 ENVIRONMENTAL FACTORS

Brown County: Above-normal rainfall was received at this location during the early portion of the growing season, but then conditions were dry throughout pod-fill. Limited, but beneficial, rainfall in August and early September enabled a few of the entries to produce yields near 40 bushels per acre.

Shawnee County: Good growing conditions occurred early in the season. Conditions became dry in August and September, but application of irrigation water resulted in higher yields than in 1998.

Franklin County: Rainfall was above normal during the early portion of the growing season, but moisture was limiting through most of the reproductive period. Dry

conditions prevailed during the latter portion of August and early September, but rainfall resumed in September and permitted the plants to complete pod-fill in a fairly normal manner.

**Cherokee County:** For the second season in a row, the southeast locations experienced severe drought. Late-summer rains benefited the maturity group V entries in the Cherokee Roundup-resistant test. The soybean cyst nematode and standard trials near Columbus did not receive timely rain during pod-fill.

**Republic County:** Both the Belleville and Scandia locations experienced a dry growing season, but both irrigated and dryland yields were good. Irrigated yields at the Scandia site averaged over 8 bushels per acre more than in 1998, and yields at the Belleville dryland site were over 7 bushels per acre higher than yields last year.

**Harvey County:** During the spring, temperatures were below normal, and rainfall was well above average. Summer temperatures averaged near to or below normal. However, below-average rainfall in July, coupled with high temperatures late in the month, resulted in severe drought stress. August also presented stressful conditions with rainfall somewhat below normal. September became unusually wet. October turned very dry and allowed for excellent harvest conditions following a light frost on October 4<sup>th</sup> and a killing frost on October 18<sup>th</sup>. No disease or insect infestations of significance were noted.

**Sumner County:** From planting to harvest, this location received minimal rainfall. With average to above-average temperatures and below-average precipitation, this test experienced moderate to severe drought stress throughout the growing season.

**Stafford County:** Plant development and

yield potential were much improved in this season compared to the performance in 1998.

**Thomas County:** Good growing conditions existed at this site with above-normal rainfall throughout June, July, and August. Heavy rain totaling 3.5 inches and hail on June 11 did result in approximately 15% leaf loss, but impact on final seed yields appeared negligible.

**Finney County:** Both the standard and Roundup-resistant trials received a severe hailstorm on July 1, which totally destroyed the canopy of many entries and adversely affected all the plots. Results are not included in this year's report.

**Ellis County:** Environmental conditions and rodents destroyed many of the plots, forcing us to abandon the trial. No results are included in the report.

**Greeley County:** Overall growing conditions were good with above-normal rainfall in July and August during pod-fill.
